Complexity, Asymptotic notation

50.004 Introduction to Algorithm

Gemma Roig

(slides adapted from Dr. Simon LUI)

ISTD, SUTD

Basic definitions

- What is a **Computational problem**:
- Map an input (e.g. x) to an output (e.g. $f(x)$)

Basic definitions

- e.g. $f(x)$ = shortest distance from Orchard to x
 - If x = “Expo”, $f(x)$ = shortest distance from Orchard to Expo
 - If x = “Changi”, $f(x)$ = shortest distance from Orchard to Changi
- So, given x , we want to **COMPUTE** $f(x)$
- A good algorithm can compute $f(x)$ quickly

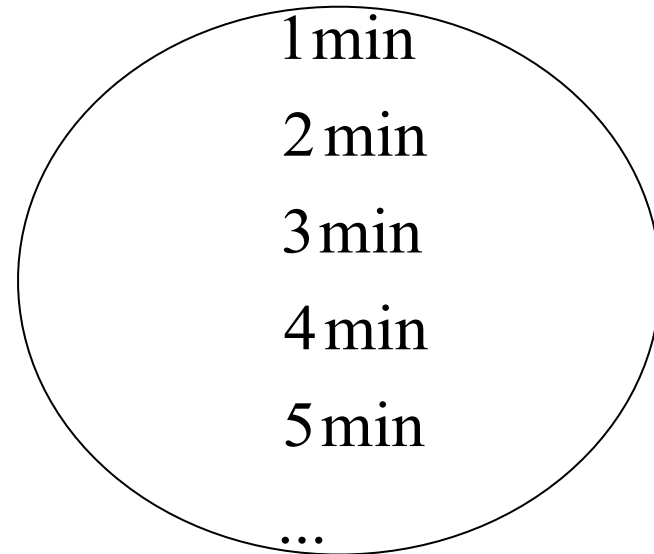

Basic definitions

- What is an **input space**
 - Set of possible input (e.g. input space = {expo, changi, Tanah Merah})
- What is an **input instance**
 - A **particular input** of a problem instance (e.g. $x = \text{expo}$)
- What is an **output space**
 - Set of possible output (e.g. output space = any positive number)

Basic definitions

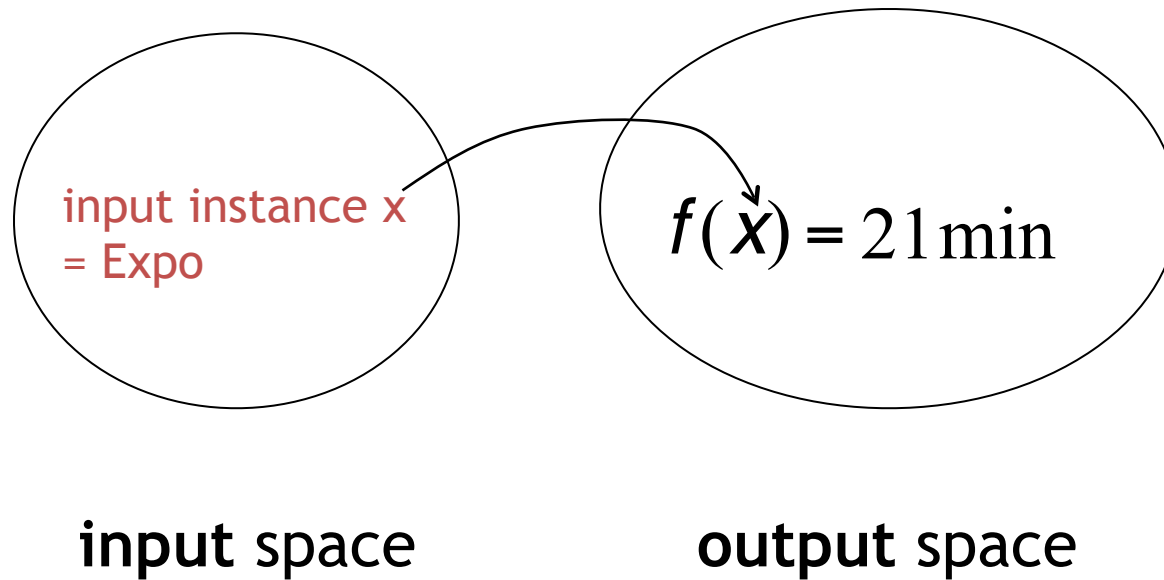

input space

output space

Basic definitions

Exercise 1

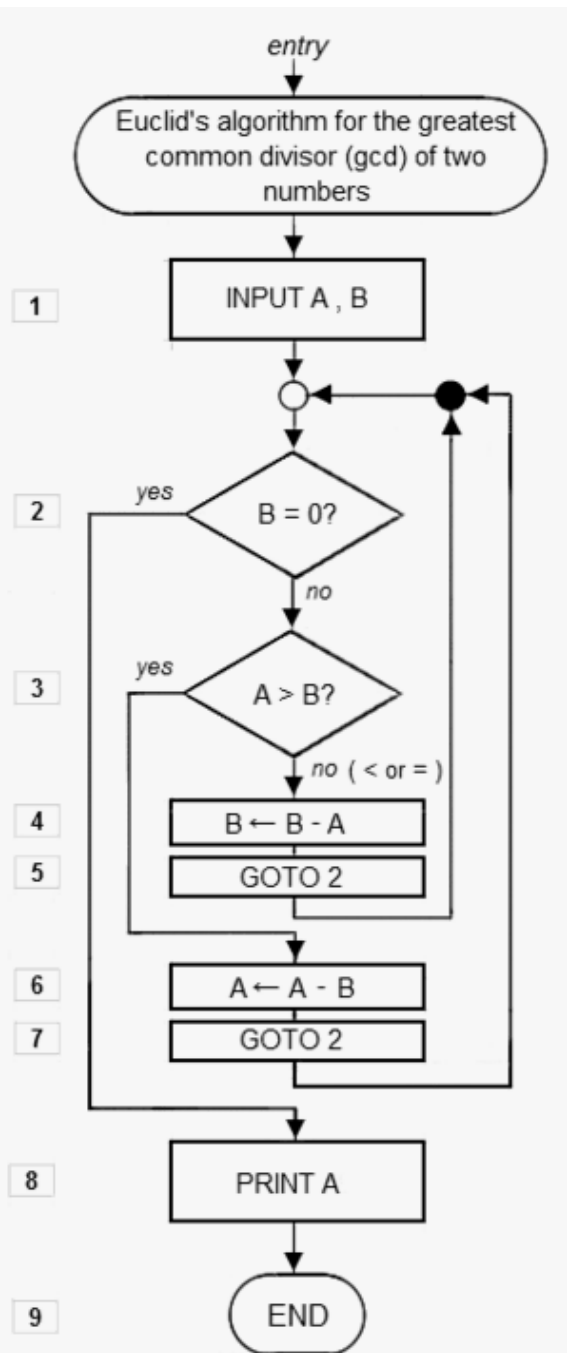

- Define the input + output space, and give an example of an input instance for the following problems
 1. Integer multiplication
 2. Find if a given integer k is in a list of n integers $[k_1, k_2, \dots, k_n]$
 3. Sort a list of n integers in increasing order
- What is the “size” of the input instance in each case? “Bigger” question = more work required to answer

Algorithm

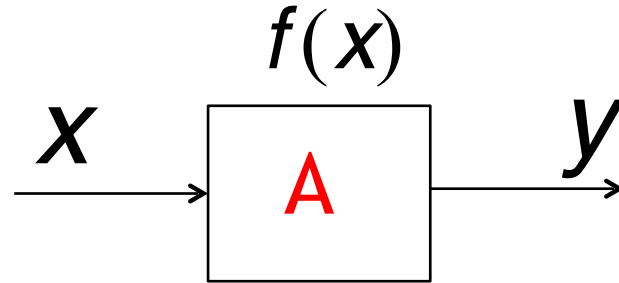

- **Procedure** for solving a computational problem
- Usually a **finite sequence of operations**
 - described in structured English
 - pseudocode or real code

Algorithm

- Example

Property of algorithm

$|x|$ = "size" of problem instance = n

$T(n)$ = number of steps to solve

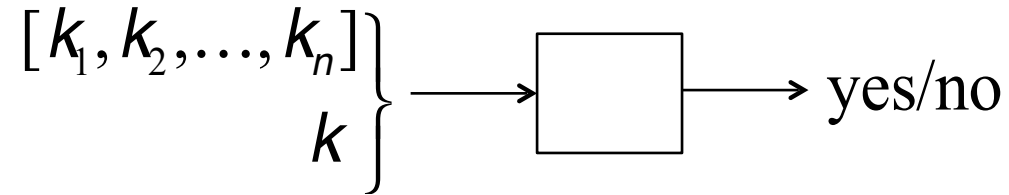

the problem as a function of its size

A Good Algorithm

- Correct
- Fast
 - For a good algorithm, $T(n)$ should increase “slowly”
as n grows

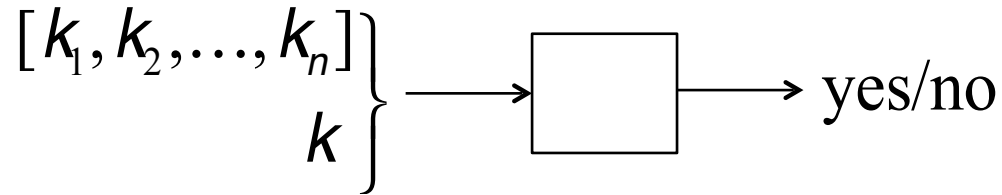

Algorithmic time complexity $T(n)$

Example **P**: Is the number k in a list of n numbers?

Algorithmic time complexity $T(n)$

Example **P**: Is the number k in a list of n numbers?

- Algorithm **A1**: check for each element k_i of the list if $k_i = k$
- How much time does A1 takes? (i.e. What is $T(n)$?)
- $T(n)$ is the exact number of steps it takes to run A1 (e.g. $T(n) = 1002$ times. e.g. $T(n)=3045$ times)

Asymptotic complexity

- The asymptotic complexity describes $T(n)$, as n grows to infinity
- In this course, we talk about THREE types of Asymptotic complexity
 - Θ (Big Theta)
 - O (Big O)
 - Ω (Big Omega)

Asymptotic complexity

- Θ (Big Theta) means “grows asymptotically = ”
- O (Big O) means “grows asymptotically \leq ”
- Ω (Big Omega) means “grows asymptotically \geq ”

Asymptotic complexity

- Θ (Theta) means “grows asymptotically equal ”
- For example

$$n^2 = \Theta(n^2)$$

- For example

$$0.1n^2 - 100n^{1.9} + 5 = \Theta(n^2)$$

- $F(x) = \Theta(G(x))$ means “F grows **as** G, when x grows to infinity”

Asymptotic complexity

- O (Big O) means “grows asymptotically \leq ”

- For example

$$n^2 = O(n^{1000})$$

- For example

$$2n^3 + 100n^2 + 5 = O(n^{3000000})$$

- $F(x) = O(G(x))$ means “ F grows **at most** as fast as G , when x grows to infinity”

Asymptotic complexity

- Ω (Omega) means “grows asymptotically \geq ”

- For example

$$n^{9999} = \Omega(1)$$

- For example

$$2n^{999999} + 100n^{33} + 5 = \Omega(n^2)$$

- $F(x) = \Omega(G(x))$ means “F grows **at least** as fast as G, when x grows to infinity”

Quick Exercises

$$(1.01)^x = ?(x^{10} \log x)$$

$$x \log \log x = ?(x^{1.5})$$

$$x^2 + x(\log x)^2 = ?(x^2)$$

Hints, asymptotic increasing order (slow to quick)
 $\log(\log x)$, $\log x$, x , x^k , k^x , x^x

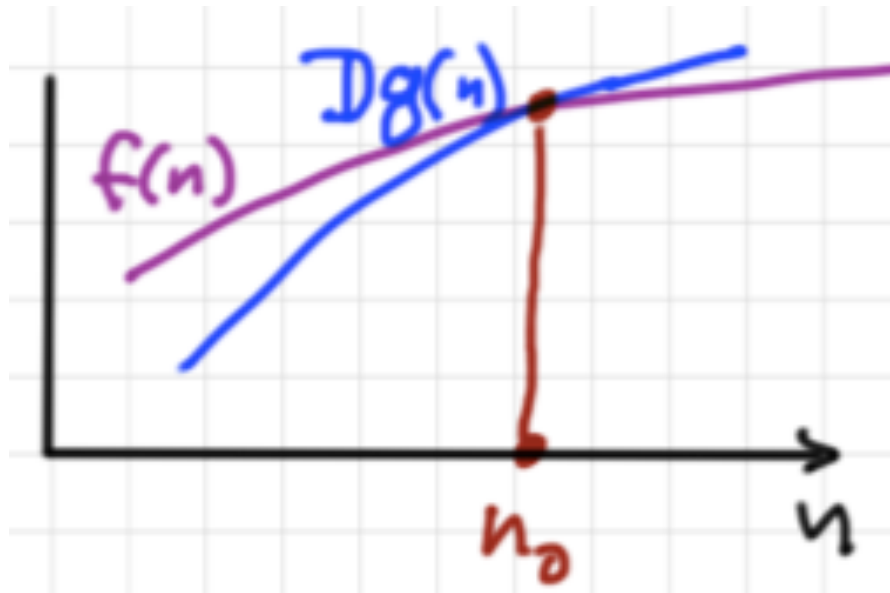

Exact definitions

$$f(n) = O(g(n)) \Leftrightarrow$$

$\exists D > 0, n_0$ such that

$$|f(n)| \leq D|g(n)| \text{ for } n \geq n_0$$

$f(n)$ when n is infinite, will not grow faster than $Dg(n)$.
 $Dg(n)$ is the upper limit

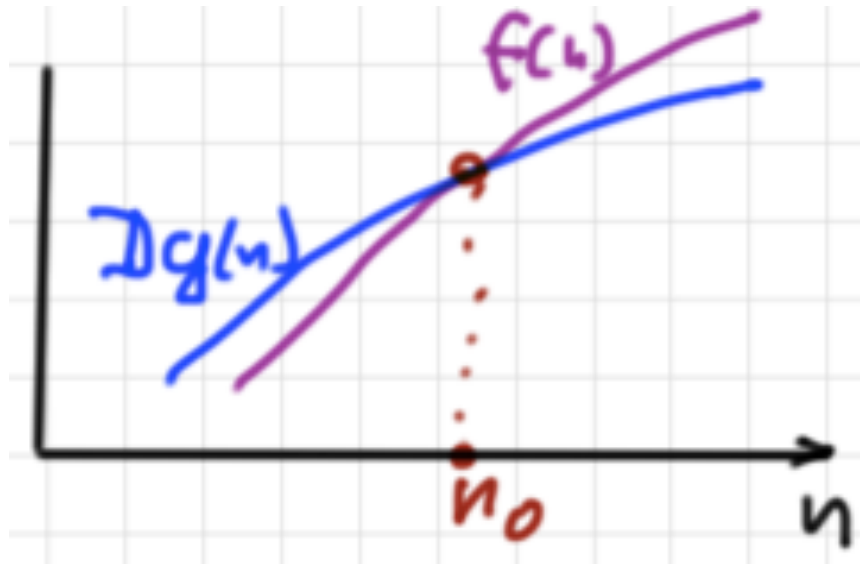

Exact definitions

$$f(n) = \Omega(g(n)) \Leftrightarrow$$

$\exists D > 0, n_0$ such that

$$|f(n)| \geq D|g(n)| \text{ for } n \geq n_0$$

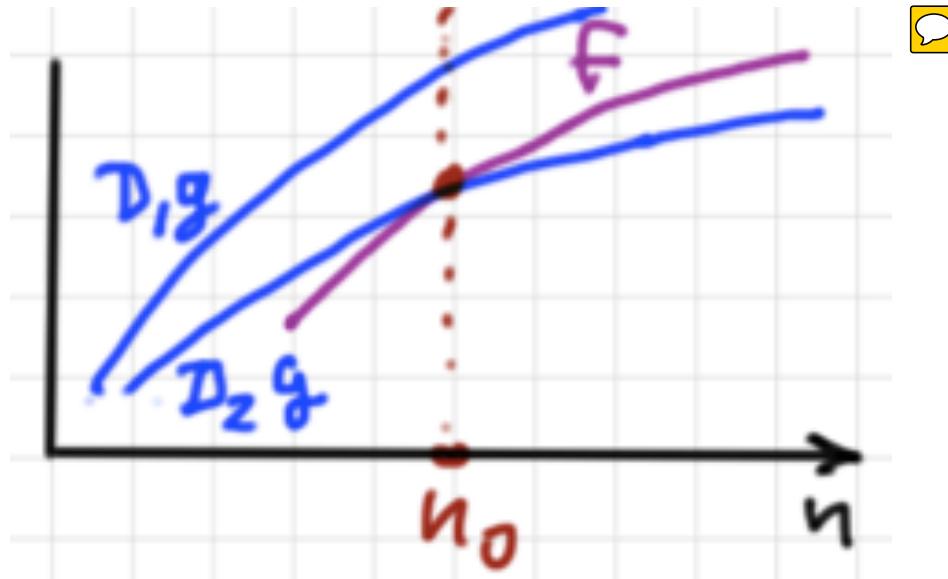

Exact definitions

$$f(n) = \Theta(g(n)) \Leftrightarrow$$

$\exists D_1, D_2 > 0, n_0$ such that

$$D_1 |g(n)| \leq |f(n)| \leq D_2 |g(n)| \text{ for } n \geq n_0$$

Exact definitions

Examples

$$f(n) = 100n + 1000$$

$$g(n) = n^2$$

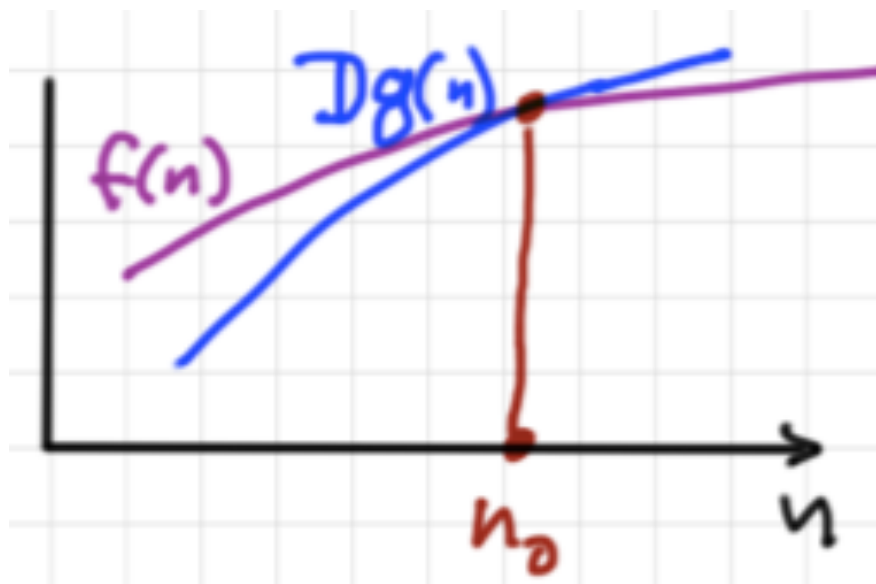

$$\text{so, } f(n) = O(g(n))$$

$$f(n) = O(g(n)) \Leftrightarrow$$

$\exists D > 0, n_0$ such that

$$|f(n)| \leq D|g(n)| \text{ for } n \geq n_0$$

$D=1$

Exact definitions

$$f(n) = 0.001n$$

$$g(n) = n^{0.5} + 1000$$

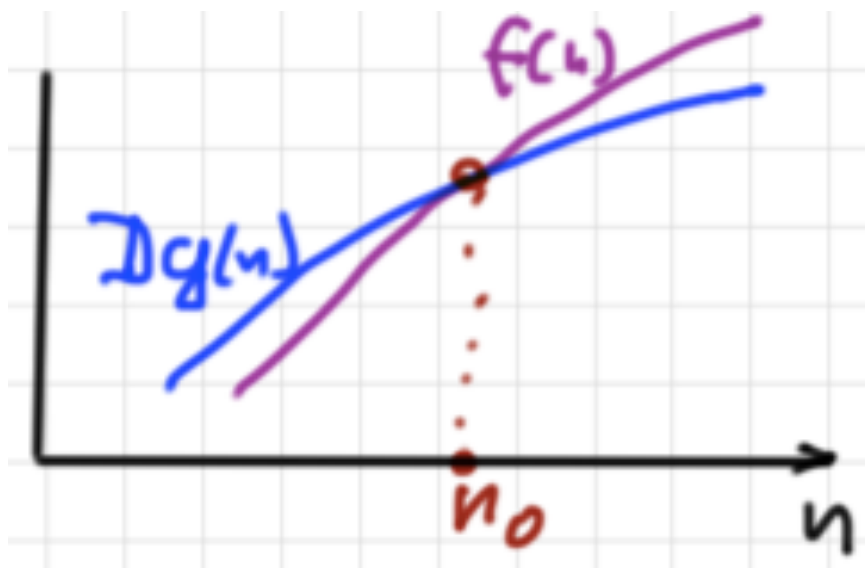

$$\text{so, } f(n) = \Omega(g(n))$$

$$f(n) = \Omega(g(n)) \Leftrightarrow$$

$$\exists D > 0, n_0 \text{ such that}$$

$$|f(n)| \geq D|g(n)| \text{ for } n \geq n_0$$

$$D=0.001$$

Exact definitions

$$f(n) = 2n^2 + 100n - 1000$$

$$g(n) = n^2$$

$$\text{so, } f(n) = \Theta(g(n))$$

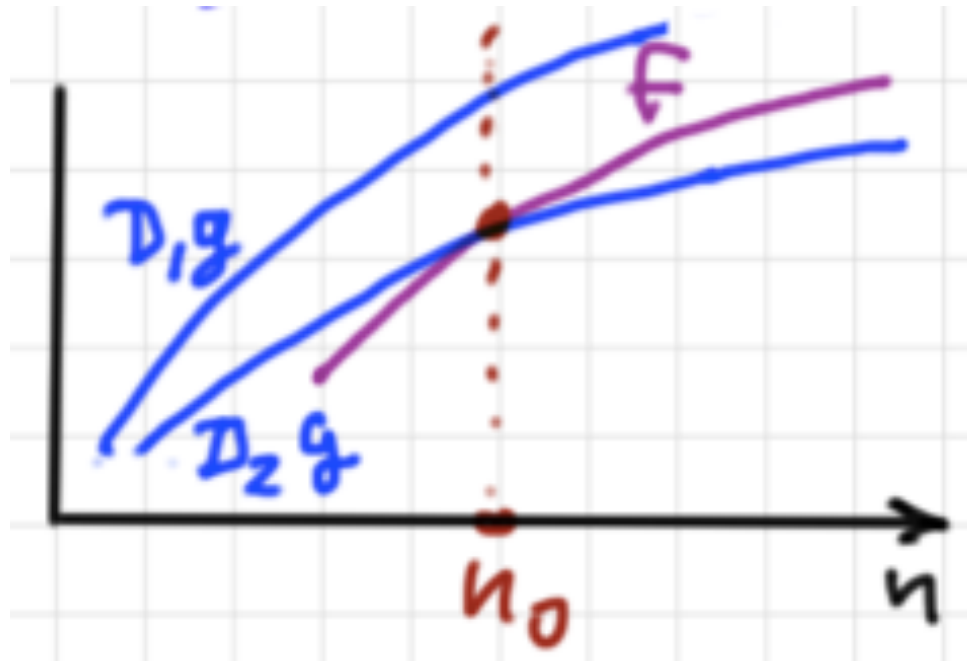

$$f(n) = \Theta(g(n)) \Leftrightarrow$$

$\exists D_1, D_2 > 0, n_0$ such that

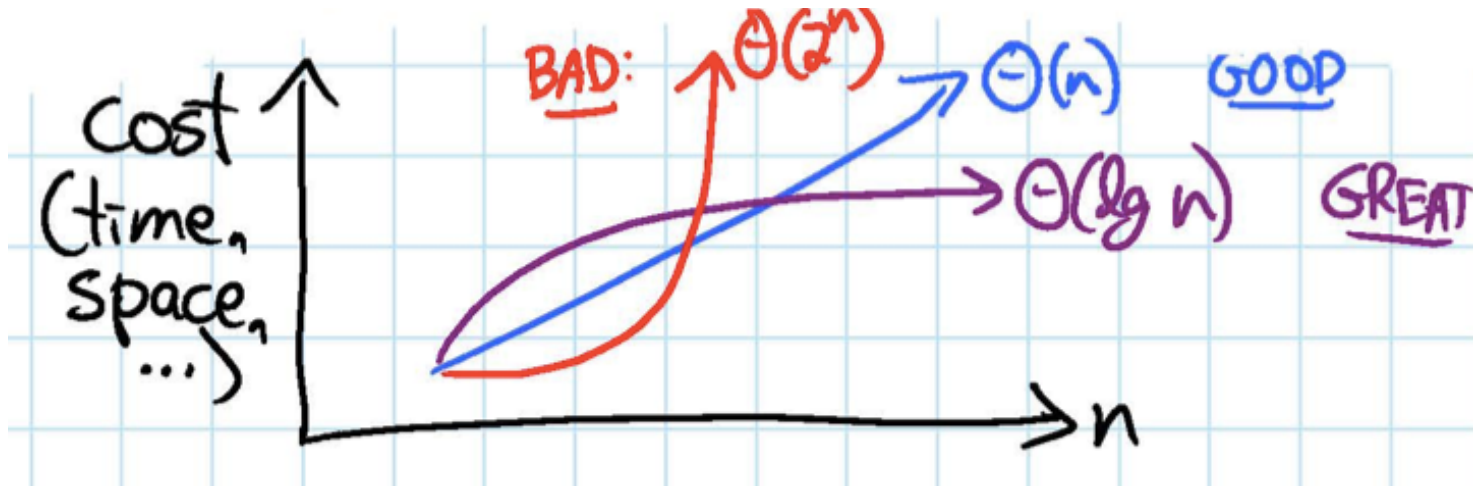

$$D_1 |g(n)| \leq |f(n)| \leq D_2 |g(n)| \text{ for } n \geq n_0$$

$$D_1 = 2$$

$$D_2 = 1$$

Complexity of algorithms

In simple and practical words used in the industry

$\Theta(\lg n)$: great algorithm

$\Theta(n)$, $\Theta(n \lg n)$, $\Theta(n^2)$: good algorithm

$\Theta(n^3)$: hard to say....

$\Theta(2^n)$: bad algorithm

Conclusions

- Key concepts:
 - Problem
 - Space and instance
 - algorithm
 - properties of algorithms
 - asymptotic complexity (Θ , O , Ω)
